

# Three-Tier Applications

In this lesson, you will learn about the three-tier applications.

*Three-tier* applications are pretty popular and largely used in the industry. Almost all simple websites like blogs, news websites etc. are part of this category.

In a *three-tier* application, the *user interface*, application logic, and the *database* all lie on different machines and, thus, have different *tiers*. They are physically separated.

So, let's take the example of a simple blog. The user interface would be written using *HTML*, *JavaScript*, or *CSS*, the backend application logic would run on a server like *Apache* and the *database* would be *MySQL*. A three-tier architecture works best for simple use cases.

Alright! Now, let's move on to learn about the *N-tier* applications.
